Predicting Heart Disease

The heart dataset (source: UCI Machine Learning Repository) contains 920 observations and 76 variables. However, we're only using the following 14 of the 76 variables in our study:

- age: patient age (in years)
- sex: gender of patient; 0 = male, 1 = female
- cp: chest pain type; 1 = typical angina, 2 = atypical angina, 3 = non-anginal pain, 4 = asymptomatic
- trestbps: resting blood pressure (in mmHg)
- chol: serum cholesterol (in mg/dl)
- fbs: fasting blood sugar > 120 mg/dl; 0 = false, 1 = true
- restecg: resting electrocardiographic results; 0 = normal, 1 = having ST-T wave abnormality, 2 = showing probable or definite left ventricular hypertrophy by Ester's criteria
- thalach: maximum heart race achieved
- exang: exercise included angina; 0 = no, 1 = yes
- oldpeak: ST depression induced by exercise relative to rest
- slope: the slope of the peak exercise ST segment; 1 = upsloping, 2 = flat, 3 = downsloping
- ca: number of major vessels (0-3) colored by fluoroscopy
- thal: thalassemia; 3 = normal, 6 = fixed defect, 7 = reversible defect
- num: diagosis of heart disease; 0 = no heart disease, 1 = have heart disease
